Dual Mode PWM/Linear Buck Converter

The NCP1501 is a dual mode regulator that operates either as a PWM Buck Converter or as a Low Drop Out Linear Regulator. If a synchronization signal is present, the NCP1501 operates as a current mode PWM converter with synchronous rectification. The synchronization signal allows the user to control the location of the spurious frequency noise generated by a PWM converter. Linear mode is active when a synchronization signal is not present. The NCP1501 configuration allows an efficient high power operation and low noise during system sleep modes.

Features

- Synchronous Rectification for Higher Efficiency in PWM Mode
- Linear Mode Operation for Low Noise Output at Low Loads
- Integrated MOSFETs and Feedback Circuits
- Cycle–by–Cycle Peak Current Limit of 800 mA (typ)
- Automatic Switching Between PWM and Linear Mode
- Operating Frequency Range of 500 to 1000 kHz
- Optimized for Ceramic Capacitors and Low Profile Inductors
- Thermal Limit Protection
- Built-in Slope Compensation for Current Mode PWM Converter
- Fixed Output Voltages of 1.05 V, 1.35 V, 1.57 V, 1.8 V
- Shutdown Current Consumption of 0.2 µA
- Internal Soft Start
- Transistor Count: 3500
- Pb–Free Package is Available

Typical Applications

- Cellular Phones
- PDAs
- Pagers
- Supplies for DSP Cores
- Portable Applications

PIN FUNCTION DESCRIPTIONS

Pin #	Symbol	Pin Description
1	SHD	Enable Pin for the NCP1501. This pin is active high. Internal pull down resistor forces the part off if the pin is not connected on the board.
2	SYN	External Synchronization Signal Pin. The device will operate in PWM mode if a clock signal is present. The pin must be pulled low to enter LDO mode. Internal pull down resistor on pin.
3	Vo	Feedback for the NCP1501. An internal MOSFET is connected across V _O and LX for LDO mode.
4	LX	Connection for the pass devices to the inductor.
5	V _{in}	Input voltage to the NCP1501.
6	GND	Ground Connection for the device.
7	CB1	Voltage Selection Bit. Internal pull up resistor on pin.
8	CB0	Voltage Selection Bit. Internal pull down resistor on pin.

MAXIMUM RATINGS

Rating	Symbol	Value	Unit	
Maximum Voltage All Pins		V _{max}	5.5	V
Maximum operating Voltage All Pins		V _{max}	5.2	V
Thermal Resistance, Junction-to-Air		R_{\thetaJA}	240	°C/W
Operating Ambient Temperature Range		T _A	-30 to +85	°C
ESD Withstand Voltage	Human Body Model (Note 1) Machine Model (Note 2)	V _{ESD}	> 2500 > 100	V
Moisture Sensitivity		MSL	Level 1	
Storage Temperature Range		T _{stg}	-55 to +150	°C
Junction Operating Temperature Range		TJ	-30 to +125	°C

Maximum ratings are those values beyond which device damage can occur. Maximum ratings applied to the device are individual stress limit values (not normal operating conditions) and are not valid simultaneously. If these limits are exceeded, device functional operation is not implied, damage may occur and reliability may be affected.

Figure 2. Typical Circuit with the Internal Schematic

DETAILED OPERATING DESCRIPTION

The Buck regulator is a synchronous rectifier PWM regulator with integrated MOSFETs. This regulator has an LDO function for low power modes to conserve power and lower ripple voltage associated with PFM mode. The NCP1501 does not contain an internal oscillator for the switching mode. The Dual PWM/LDO mode is an exclusive Patent Pending circuit.

The PWM clock is generated via an external clock signal on the Synchronization pin. The operating frequency range for the PWM is 500 kHz to 1000 kHz. The output current of the PWM is typically 100 mA with a guarantee of over 300 mA for the 2.7 to 5.2 input voltage range.

If a synchronization pulse is not present, the NCP1501 changes into the LDO mode. The LDO function assures the user of an extremely low output ripple voltage and greatly reduced quiescent current when the users system is in a sleep mode. Internally to the NCP1501, the Synchronization pin

has a pull down resistor to force the part into LDO mode when a clock signal is not present. To place the NCP1501 in LDO mode, the user must set the Synchronization pin low. The LDO mode guarantees an output in excess of 50 mA.

Pins CB0 and CB1 control the output voltage selection. The four voltages are 1.05 V, 1.35 V, 1.57 V, 1.8 V. CB0 contains a pull down resistor and CB1 contains a pull up resistor internal to the NCP1501. The resistors force the output of the converter to 1.35 V if the pins are floating connections to the external circuit.

The Shutdown Pin enables the operation of the device. The Shutdown Pin has an internal pull down resistor to force the NCP1501 into the off mode if this pin is floating due to the external circuit. During Startup, the NCP1501 has a soft start function to limit fast dV/dt and eliminate overshoot on the output.

Figure 3. Block Diagram and Circuit Schematic of the NCP1501

The external components required are an input and an output 10 0 μ F ceramic capacitor and a 10 μ H inductor.

PWM Mode

During normal operation, a synchronization pulse acts as the clock for the DC/DC controller. The rising edge of the clock pulls the gate of Q1 low allowing the inductor to charge. When the current through Q1 reaches either the current limit or feedback voltage reaches its limit, Q1 will turn off and Q2 will turn on. Q2 replaces the free wheeling diode typically associated with Buck Converters. Q2 will turn off when either a rising edge sync pulse is present or all the stored energy is depleted from the inductor. Q3 remains off during this mode. The output voltage accuracy in the PWM mode is well within 3% of the nominal set value. An over voltage protection circuit is present in the PWM mode to limit the positive voltage spike due to fast load transient conditions. The PWM also has the ability to go to 100% duty cycle for transient conditions and low input to output voltage differentials.

In PWM mode, each switching cycle has a guaranteed on-time of 100 ns. The NCP1501 has two protection circuits that can eliminate the cycle. When tripped, the over voltage protection or the thermal shutdown overrides the gate drive of the high side MOSFET.

Figure 4. PWM Circuit Schematic

LDO Mode

When the synchronization pulse is not present, the NCP1501 operates as an LDO. The DC/DC Control Circuitry will relinquish control of Q1 and turn off Q2. The

LDO Control Circuitry will turn on Q3 as a bypass circuit to the inductor. Q1 is the controlling pass device of the LDO that regulates the input to output voltage dropout. The LDO can source an output current in excess of 50 mA.

Figure 5. LDO Circuit Schematic

Voltage Output Selection

The output voltage selection is accomplished via two external pins: CB0 and CB1. If CB0 and CB1 pins are left floating by the external circuit, the output voltage will default to 1.35 V. The corresponding voltages are as follows.

		NCP1501	
CB0	CB1	V _{out} (V)	
0	0	1.05	
0	1	1.35	
1	1	1.57	
1	0	1.80	

Thermal Shutdown

Internal Thermal Shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at 160°C, the PWM latch is reset and the linear regulator control circuitry is disabled. The thermal shutdown circuit is designed with 25°C of hysteresis. This means that the PWM latch and the regulator control circuitry cannot be re-enabled until the die temperature drops by this amount. This feature is provided to prevent catastrophic failures from accidental device overheating. It is not intended as a substitute for proper heatsinking. The NCP1501 is contained in the Micro-8 package.

Figure 8. Waveforms During Normal Operation

APPLICATIONS INFORMATION

NCP1501 is a dual mode PWM or LDO step down converter. This dual mode takes advantage of the best of each mode. There are three required external components: an input and output capacitor and an inductor.

The PWM mode allows high efficiency for larger loads. A typical efficiency for an input of 3.6 V and an output of 1.8 V and 100 mA is over 90%. Low R_{DSon} and synchronous rectification contained within the device contributes to the very high efficiency. As with other synchronous rectification devices, the NCP1501 does not require an external diode to supplement the NFET during switching on or off. A synchronization pin allows the user to define the frequency noise spikes of the PWM. The duty cycle of the synchronization signal must be within the range

of 30% to 70%. The rising edge of the signal from the synchronization pin acts as the oscillator signal to set the latch and reset the ramp compensation signal. An Over Voltage Protection circuit ensures the output will respond properly to fast transients from large to small loads. The NCP1501 allows the PWM mode to enter a 100% duty cycle for fast load transient conditions and low input to output voltage differentials.

The LDO mode is effective during low load conditions by lowering the quiescent current and reducing the output ripple voltage associated with PWM converters entering PFM mode. NCP1501 enters the LDO mode when a synchronization signal is not present. It is recommended to pull the synchronization signal low for LDO mode.
